In principle, this is true also for spinor fields (e.g. the Dirac equation). However, one can choose a representation in which the Dirac equation has a relatively simple form, for instance: $$ i\gamma^\mu \frac{\partial \psi}{\partial x^\mu} - m\psi=0$, where γ^μ are the gamma matrices and m is a free parameter. Question: can we add higher order derivative terms to the action? More generally, how is the quantization of spinor fields affected by the choice of representation? A: The quantization of spinor fields is not limited to the Dirac equation. In fact, one can generalize to all first-order systems of partial differential equations, like this (we limit ourselves to Lorentz covariant fields, but the statement holds for general covariant equations): (i\partial_\mu + A_\mu) \psi = 0, \tag{QED} where ψ is a scalar field of the same dimensionality as A_μ and A_μ is a vector potential. The standard way to proceed is to treat (QED) as an eigenvalue 82157476af
